

The New Universe

MEMPHIS, SUNDAY OCTOBER 23, 2022

WHAT DO EXPENSIVE NEW TELESCOPES DO FOR HUMANITY TODAY?

Are mega-projects like ALMA, LIGO, JWST, and Gaia worth the billions?

ARE COMPUTERS THE NEW TELESCOPES?

New galaxies in-silico, the early Universe “learned” without physics, and new stars forming in your hand.

IS ASTROPHYSICS BEING (RE)ORGANIZED?

Lone stargazers are a rarer and rarer breed in professional astronomy. Teams and data scientists seem the way of the future, and tools that talk to each other are essential.

Key Category	ASTRONOMY IN 1992	ASTRONOMY IN 2022	SO WHAT?	
Discovery	The Universe is likely decelerating.	The Universe is accelerating .	Oh no, dark energy AND dark matter! Or MOND?	Nobel 2011
Discovery	gravity waves were theoretical	gravitational-wave detections (LIGO) give rise to true “multi-messenger” astrophysics	wide range of discoveries in studies of “compact” objects, where general relativity is best tested, observation of gravity waves	Nobel 2017
Discovery	no planets known beyond the Solar System, circumstellar disks barely detected	Thousands of exoplanets , brilliant images of disks forming them	(exoplanetology+exoclimatology+ astrobiology)=humans can legitimately study the Origins of Life in the Universe	Nobel 2019
Discovery	black holes were theoretical	black holes observed in the center of the Milky Way, and in other galaxies, using high-resolution time-resolved observations	significant tests of general relativity , all of which have been passed (no huge surprises—bad for MOND)	Nobel 2020
Technology	spectroscopy one spectrum at a time	MANY spectra at a time : focal-plane arrays, fiber-fed spectrographs, interferometers, IFUs	thousands or more spectra simultaneously, instead of 1 at a time give details on motion & composition of all components of the Universe	♥
Technology	UNIX, LaTeX on Suns, MacOS best for graphics	Python on anything, many other languages, collaboration via Jupyter notebooks etc.	Astronomy=Data Science ; HUGE wealth of new techniques enabling new discoveries (Bayesian statistics, Machine Learning, much more...)	♥
Technology	early supercomputers (CRAY)	ubiquitous super-fast, cheap, high-performance computing	Simulation an essential “third branch” of astronomy beyond “observations” and “theory”	♥
Technology	IRAS success, Hubble launched, mirror flawed	numerous space missions, some HUGE (e.g. JWST)	multi-wavelength coverage, ultra-sharp, ultra deep images , w/n concern about atmospheric effects	♥
Technology	infrared cameras with 4 MP were “amazing”	JWST NIRCam camera has 122 million pixels	MUCH higher resolution, over wider areas	♥
Technology	software one-offs, except for big projects	open source, modular software	re-usable code, “ Seamless Astronomy ”	♥
Technology	draftspeople draw graphs	computer graphics for all, even interactive, and augmented reality	Explore-Explain approach made possible by rich data display	♥
Technology	Exploratory Data Analysis: DataDesk	Exploratory Data Analysis: glueviz	Explore-Explain approach made possible by rich data interactions	♥
Technology	glass plate archives, disks, tapes	Internet access to “all” data (e.g. WWT, SA Sky et al.)	“Seamless Astronomy” made possible by ready data access	♥
Technology	3D meant “position-position-velocity” space, at best, except in Hubble flow or rare astrometric measurements	3D means 3D: Gaia for stars, 3D Dust for ISM	unprecedented maps of the Milky Way’s gas, dust, and stars, in true 3D (sometimes even 4D, 5D or 6D!)	♥
Nature of Science	interest in outreach/education in astronomy research by scientists	outreach components of PhDs & postdocs desirable, or even required	improvement in SciComm? (CommSciCom)	♥
Technology	printed indices in journals used to search literature	ADS launched 1992, arxiv, 1991, ADS All-Sky Survey 2012	find any literature , including on the Sky, more “ Seamless Astronomy ”	
Technology	X-rays detected, not quite images	X-ray images (Chandra launched 1999)	MUCH higher sensitivity in detectors, seeing “fainter objects”	
Technology	actual telescope observing, in real-time	remote telescope observing, queue scheduling	telescope access expanded , <i>but</i> students less well-trained in mechanics of observing	
Nature of Science	Astronomy ~80% white males	Fraction of non-white non-male astronomers ~40%	diversity of approaches to science and how to be a scientist, more role models	
Nature of Science	secret science the norm	open-science more popular	improved data re-use and reproducibility ; astronomy as a poster-child	♥
Funding	funding proposal success 30-50%	funding proposal success 5-15%	much harder to secure funding ; more time spent writing proposals	
Funding	expensive telescope= tens of millions (until Hubble)	expensive telescopes = billions	fewer opportunities for hands-on observing, and for training “instrumentalists” — higher and higher stakes for space-based missions	
Technology	glass plate measuring machines used to do “astrometry”	astrometry.net (2012), Gaia 2018	“register” positions of astrophysical sources and images with ease	
Nature of Science	typical collaboration size ~5 people at most, except large instrument projects	collaboration size often >>10 people , often international	<i>difficulty</i> in assigning “ credit ” to individuals	

I will NOT subject you to this, but the slides will be online in case you'd like to know more about the past 30 years of Astronomy!

THE NEW YORK TIMES, TUESDAY, JANUARY 25, 2022

OUT THERE | DENNIS OVERBYE

Where Our Bubble Ends, Our Understanding Begins

By mapping a region devoid of gas and dust, scientists learn more about star formation.

JUST A BIT TOO LATE for New Year celebrations, astronomers have discovered that the Milky Way galaxy, our home, is, like champagne, full of bubbles.

As it happens, our solar system is passing through the center of one of these bubbles. Fourteen million years ago, according to the astronomers, a firecracker chain of supernova explosions drove off all the gas and dust from a region roughly 1,000 light-years wide, leaving it bereft of the material needed to produce new generations of stars.

As a result, all the baby stars in our neighborhood can be found stuck on the edges of this bubble. There, the staccato force of a previous generation of exploding stars has pushed gas clouds together into forms dense enough to collapse under their own ponderous if diffuse gravity and condense enough to ignite, as baby stars. Our sun, 4.5 billion years old, drifts through the middle of this space in a coterie of aged stars.

"This is really an origin story," Catherine Zucker said in a news release from the Harvard-Smithsonian Center for Astrophysics. "For the first time, we can explain how all nearby star formation began."

Dr. Zucker, now at the Space Telescope Science Institute in Baltimore, led a team that mapped what they call the Local Bubble in remarkable detail. They used data from a number of sources, particularly Gaia, a European spacecraft, that has mapped and measured more than a billion stars, to pinpoint the locations of gas and dust clouds.

Last year, a group of scientists led by João Alves, an astrophysicist at the University of Vienna, announced the discovery of the Radcliffe Wave, an undulating string of dust and gas clouds 9,000 light-years long that might be the spine of our Local arm of the galaxy. One section of the wave now appears to be part of our Local Bubble.

The same group of scientists published their latest findings in *Nature*, along with an elaborate animated map of the Local Bubble and its highlights.

The results, the astronomers write, provide "robust observational support" for a long-held theory that supernova explosions are important in triggering star formation, perhaps by jostling gas and dust clouds into collapsing and starting on the long road to thermonuclear luminosity.

Astronomers have long recognized the Local Bubble. What is new, said Alyssa Goodman, a member of the team also from the Harvard-Smithsonian Center for Astrophysics, is the observation that all local star-forming regions lie on the Local Bubble's surface. Researchers previously lacked the tools to map gas and dust clouds in three dimensions. "Thanks to 3-D dust-mapping, now we do," Dr. Goodman said.

According to the team's calculations, the

NYT, January 25, 2022

Above an illustration of the Local Bubble, which formed in the Milky Way, left, when supernova explosions drove off all the gas and dust from a 1,000-light-year-wide region.

Local Bubble began 14 million years ago with a massive supernova, the first of about 15 massive stars that died and blew up. Their blast waves cleared out the region. There are now no stars younger than 14 million years in the bubble, Dr. Goodman said.

The bubble continues to grow at about 4 miles a second. "Still, more supernovae are expected to take place in the near future, like Antares, a red supergiant star near the edge of the bubble that could go any century now," Dr. Alves said. "So the Local Bubble is not done."

With a score of well-known star-forming regions sitting on the surface of the bubble, the next generation of stars is securely on tap.

The team plans to go on and map more bubbles in the our Milky Way flate of champagne. There must be more, Dr. Goodman said, because it would be too much of a coincidence for the sun to be smack in the middle of the only one.

The sun's presence in this one is nonetheless coincidental, Dr. Alves said. Our star wandered into the region only five million years ago — long after most of the action — and will exit about five million years from now.

The motions of the stars are more irregular than commonly portrayed, as they are bumped gravitationally by other stars, clouds and the like, Dr. Alves said.

"The sun is moving at a significantly different velocity than the average of the stars and gas in the solar neighborhood," he noted. This would enable it to catch up and pass — or be passed by — the bubble.

"It was a revelation," Dr. Goodman said, "how lanky the sun's path really is compared with a simple circle."

Article

Star formation near the Sun is driven by expansion of the Local Bubble

<https://doi.org/10.1038/s41586-021-04286-5>

Received: 18 August 2021

Accepted: 26 November 2021

Catherine Zucker^{1,2}✉, Alyssa A. Goodman¹, João Alves³, Shmuel Bialy^{1,4}, Michael Foley¹, Joshua S. Speagle^{5,6,7}, Josefa Großschedl³, Douglas P. Finkbeiner^{1,8}, Andreas Burkert^{9,10}, Diana Khimey¹ & Cameren Swiggum^{3,11}

For decades we have known that the Sun lies within the Local Bubble, a cavity of low-density, high-temperature plasma surrounded by a shell of cold, neutral gas and dust^{1–3}. However, the precise shape and extent of this shell^{4,5}, the impetus and timescale for its formation^{6,7}, and its relationship to nearby star formation⁸ have remained uncertain, largely due to low-resolution models of the local interstellar medium. Here we report an analysis of the three-dimensional positions, shapes and motions of dense gas and young stars within 200 pc of the Sun, using new spatial^{9–11} and dynamical constraints¹². We find that nearly all of the star-forming complexes in the solar vicinity lie on the surface of the Local Bubble and that their young stars show outward expansion mainly perpendicular to the bubble's surface. Tracebacks of these young stars' motions support a picture in which the origin of the Local Bubble was a burst of stellar birth and then death (supernovae) taking place near the bubble's centre beginning approximately 14 Myr ago. The expansion of the Local Bubble created by the supernovae swept up the ambient interstellar medium into an extended shell that has now fragmented and collapsed into the most prominent nearby molecular clouds, in turn providing robust observational support for the theory of supernova-driven star formation.

Fig. 1 | A 3D spatial view of the solar neighbourhood. For the best experience, please view the online 3D interactive version available in Supplementary Fig. 1. **a**, A top-down projection of star-forming regions on the surface of the Local Bubble, whose young stars show motion mainly perpendicular to its surface. The surface of the Local Bubble¹³ is shown in purple. The short squiggly coloured lines (or 'skeletons') demarcate the 3D spatial morphology of dense gas in prominent nearby molecular clouds¹¹. The 3D arrows indicate the positions of young stellar clusters, with the apex of the arrow's cone pointing in the direction of stellar motion. Clusters are colour-coded by longitude, as in Extended Data Table 1. The Sun is marked with a yellow cross. The enlargement to the lower right shows a close-up of Ophiuchus, Pipe, Lupus and Corona

Australis on the bubble's surface, along with arrows illustrating the outward motion of their young stellar clusters. **b**, A 3D view of the relationship between the Local Bubble, prominent nearby star-forming regions and Galactic structure. The Local Bubble and cloud skeletons are the same as in **a**. We also overlay the morphology of the 3D dust (grey blobby shapes⁹) and the models for two Galactic scale features—the Radcliffe Wave (red)¹⁶ and the Split (blue)¹⁰. The Per-Tau Superbubble¹⁵ (green sphere) is also overlaid. The interactive version offers views from any direction (not just top-down), provides floating labels for star-forming regions and includes additional layers (some not shown in this snapshot), which can be toggled on/off.

Alsacian Streusel Crisp

Source: myparisiankitchen.com

★★★★★ 8 serves Prep: 10 mins Cook: 20 mins 7 Ingredients

Description
Streusel is a traditional crumble topping from East France Alsace. Cinnamon and hazelnut or almond powder are added to the classic butter – sugar – flour mix.

Ingredients
125 g butter cold and cubbed
125 gr raw sugar
125 gr flour
125 gr hazelnut powder

Method

- In a bowl, combine flour, raw sugar, hazelnut powder, salt, and the teaspoon (or two!) of ground cinnamon. Combine well all these dry powders.
- Eventually, add diced dried fruit and/or crunched nuts.
- Add the cubed butter. Mix with your fingertips until you get a sandy texture. You can also mix the dough with a food processor.

AI-assisted superresolution cosmological simulations

Yin Li , Yueying Ni , Rupert A. C. Croft ,  ⁺², and Yu Feng [Authors Info & Affiliations](#)

Edited by Neta A. Bahcall, Princeton University, Princeton, NJ, and approved March 11, 2021 (received for review October 26, 2020)

May 4, 2021 | 118 (19) e2022038118 | <https://doi.org/10.1073/pnas.2022038118>

Significance

Cosmological simulations are indispensable for understanding our Universe, from the creation of the cosmic web to the formation of galaxies and their central black holes. This vast dynamic range incurs large computational costs, demanding sacrifice of either resolution or size and often both. We build a deep neural network to enhance low-resolution dark-matter simulations, generating superresolution realizations that agree remarkably well with authentic high-resolution counterparts on their statistical properties and are orders-of-magnitude faster. It readily applies to larger volumes and generalizes to rare objects not present in the training data. Our study shows that deep learning and cosmological simulations can be a powerful combination to model the structure formation of our Universe over its full dynamic range.

IS EINSTEIN'S THEORY OF GRAVITY ENOUGH?

KAGRA

KAGRA's Y-arm under construction. (KAGRA)

Japan is currently building a 3 km interferometer inside of the Kamioka mine (also home to the Super Kamiokande neutrino detector). Being underground, the detector will be exposed to much less seismic vibration than surface instruments like LIGO, Virgo and GEO600. **KAGRA** will also use cryogenic systems, meaning that the optics will be cooled to such a degree that molecular vibrations within the material itself will be brought almost to a stop (the key to detecting gravitational waves is to isolate the detector from any and all Earthly vibrations that might mimic or mask a gravitational wave vibration; that includes vibrating molecules in mirrors and their coatings). Full-scale operation of this observatory is expected to commence in 2020.

Testing Einstein's theory of gravity from the shadows and collisions of black holes

by Ethan Payne, ARC Centre of Excellence for Gravitational Wave Discovery

Artist's impression of binary black holes about to collide. Credit: Mark Myers, OzGrav-Swinburne Univer...

General relativity, Einstein's theory of gravity, is best tested at its most extreme—close to the event horizon of a black hole. This regime is accessible through observations of shadows of supermassive black holes and gravitational waves—ripples in the fabric of our Universe from colliding stellar-mass black holes. For the first time, scientists from the ARC Center of Excellence for Gravitational Wave Discovery (OzGrav), the Event Horizon Telescope (EHT) and the LIGO Scientific Collaboration, have outlined a consistent approach to exploring deviations from Einstein's general theory of relativity in these two different observations. This research, published in *Physical Review D*, confirms that Einstein's theory accurately describes current observations of black holes, from the smallest to the largest.

Astronomers Gear Up to Grapple with the High-Tension Cosmos

A debate over conflicting measurements of key cosmological properties is set to shape the next decade of astronomy and astrophysics

By Anil Ananthaswamy

*“These twin tensions—between expectation and observation, between the early and late universe—may reflect some **deep flaw in the Standard Model of cosmology**, which encapsulates our knowledge and assumptions about the universe. Finding and fixing that flaw could transform our understanding of the cosmos.”*

The third generation is only now starting to take the stage with the successful launch and deep-space deployment of Hubble's successor, the James Webb Space Telescope (JWST). On Earth, radio telescope arrays such as the Simons Observatory in the Atacama Desert in Chile and the CMB-S4, a future assemblage of 21 dishes and half a million cryogenically cooled

because these are independent observatories,” says astrophysicist Priyamvada Natarajan of Yale University. “Even if we have a systematic in our framework, we should [be able to] figure it out.”

Science is so much more than equations and lab coats. It requires human creativity, ingenuity, argument, and persistence.

The Path-to Foundation's goal is to deepen students', scientists', and the broader public's appreciation of science by telling stories of its history.

The New Universe

MEMPHIS, SUNDAY OCTOBER 23, 2022

WHAT DO EXPENSIVE NEW TELESCOPES DO FOR HUMANITY TODAY?

Are mega-projects like ALMA, LIGO, JWST, and Gaia worth the billions?

ARE COMPUTERS THE NEW TELESCOPES?

New galaxies in-silico, the early Universe “learned” without physics, and new stars forming in your hand.

IS ASTROPHYSICS BEING (RE)ORGANIZED?

Lone stargazers are a rarer and rarer breed in professional astronomy. Teams and data scientists seem the way of the future, and tools that talk to each other are essential.

Thanks.
